

The arc. Yue Mei began around 2010 in China working on surface mechanics and capillarity with Jianlin Liu — very different from where he is now. Around 2014 he moved to Texas A&M for a PhD with Sevan Goenezen, where he pivoted into elastography and inverse elasticity — the origin of his current research identity, and the same Goenezen whose 2021 experimental-elastography paper sits as reference [38] in the Wei paper we analyzed. During that period he also had Swansea visits with Chennakesava Kadapa at the Zienkiewicz Centre, building his computational-mechanics chops. A sustained French collaboration with Stéphane Avril at Mines Saint-Étienne opened around 2017 and runs in parallel to this day. Around 2019–2020 he moved back to China as faculty at Dalian University of Technology, joining Xu Guo’s group — one of the world’s most productive topology-optimization labs. Productivity exploded to ten-plus papers a year, and he began hybridizing elastography inverse problems with topology optimization — the Wei paper is a clean example of that hybridization. Most recently (2025–2026) he has pivoted hard into deep learning — PINN, Kolmogorov–Arnold networks, physics-informed methods — and the first real experimental data in his recent output, an MRI elastography study of the human intervertebral disc.

Data: OpenAlex (ORCID 0000-0003-3469-3055). h-index 18, 91 works, 847 citations. Affiliation-based disambiguation; one Beihang-CS paper filtered out.
